Abstract

Two frequency-domain methods for predicting phonon frequencies and lifetimes using the phonon spectral energy density are described. Both methods draw input from molecular dynamics simulations and lattice dynamics calculations, but differ in the form of the phonon spectral energy density. One phonon spectral energy density expression (referred to as Φ) can be formally derived from lattice dynamics theory. A similar approach in the time domain has been validated [Turney et al. Phys. Rev. B 79, 224305 (2009)]. The other phonon spectral energy density expression (referred to as Φ') has been proposed [Thomas et al., Phys. Rev. B 81, 081411(R) (2010)] but not validated. The expressions for Φ and Φ' are presented and then applied to predict the phonon properties and thermal conductivities of three systems: Lennard-Jones argon, Stillinger-Weber silicon, and a carbon nanotube modeled using the Reactive Empirical Bond Order potential. Φ' does not capture the total phonon spectral energy density predicted by Φ and therefore cannot correctly predict the phonon lifetimes or thermal conductivity. Its use in future work is discouraged and we recommend the use of Φ.

Keywords: normal mode, phonon lifetime, phonon-phonon interactions, thermal conductivity, molecular dynamics simulations, lattice dynamics calculations
1 Introduction

Phonons are the dominant carriers of thermal energy in dielectric and semiconducting crystals [1–6]. While substantial effort has been devoted to developing theories of phonon transport, the current understanding is incomplete, even in bulk materials. For example, which phonon modes dominate thermal energy transport and the importance of interactions involving four or more phonons are still being investigated [1, 3, 4, 7, 8]. The situation becomes more complicated in nanostructures, where the phonons also interact with free surfaces and interfaces [9–21].

Analytical models of thermal transport, such as the Debye model, are limited by the necessary approximations and assumptions [18, 22, 23]. With the Green-Kubo or non-equilibrium direct methods, molecular dynamics (MD) simulations can be used to predict thermal conductivity, but only in a classical (i.e., high-temperature) framework [8, 17, 24–30]. Because the analysis in these two MD-based methods is performed at the system level, no information about the phonons is obtained. Phonon specific heats, group velocities, and lifetimes are the required inputs for predicting thermal conductivity at the phonon-mode-level using Boltzmann transport equation-based models [8, 18, 24, 25, 28, 31, 32]. These phonon properties can be predicted using harmonic and anharmonic lattice dynamics calculations [4, 6, 24, 28, 33, 34], where quantum statistical effects can be naturally included. Anharmonic lattice dynamics calculations are limited to three-phonon scattering events, however, and are thus only valid at low temperatures [3, 4, 8, 28].

At high temperature, four-phonon and higher-order processes become important to thermal transport [3, 4, 8, 28]. All orders of phonon processes are present in a
MD simulation as the positions and momenta of the atoms are evolved using the full anharmonicity of the interatomic interactions [8, 25]. Phonon properties can be predicted from a MD simulation using normal mode analysis in the time domain [24, 25, 28, 32, 35, 36]. In Section 2.1, we will describe how this approach can be performed in the frequency-domain using the phonon spectral energy density (SED, referred to as Φ). An alternative expression for the phonon SED (referred to as Φ′), was recently proposed but has not been rigorously tested [37–39]. Φ′ was first used to predict the phonon dispersion curves of carbon nanotubes (CNTs) [37]. Thomas et al. used Φ′ to predict the phonon lifetimes and thermal conductivity of isolated and water-filled CNTs, obtaining good agreement with other atomistic predictions [39]. The phonon lifetime reductions speculated for water-filled CNTs [39] and CNTs on SiO₂ substrates [40] suggest that Φ′ captures phonon physics at least qualitatively. The phonon lifetimes and thermal conductivity for PbTe [41] and Half Heusler alloys [42] have also been predicted using Φ′. De Koker predicted the phonon lifetimes and thermal conductivity for MgO using an expression similar to Φ′ (but different than Φ) [43]. Another recent atomistic study using Stillinger-Weber silicon predicted phonon lifetimes using both Φ and Φ′, but a detailed comparison of the predictions between the two was not performed [44].

The objective of this work is to assess the validity of Φ′ as a phonon SED by comparing the phonon properties it predicts to those predicted by Φ. In Section 2.1, we present the correct phonon SED (Φ), which requires the phonon mode eigenvectors. The expression for Φ is well-defined theoretically and has been tested and validated in previous studies in the time domain [24, 28]. In Section 2.2, we present the proposed
alternative expression for the phonon SED, $\Phi'$, which does not require the phonon mode eigenvector $[39]$. Phonon frequencies, lifetimes, and thermal conductivities are then predicted and compared using $\Phi$ and $\Phi'$ for three test systems: Lennard-Jones (LJ) argon $[45]$ in Section 4.1, Stillinger-Weber (SW) silicon $[46]$ in Section 4.2, and an (8,8) CNT modeled with the reactive empirical bond order (REBO) potential $[47]$ in Section 4.3. While $\Phi'$ is found to accurately predict the phonon frequencies, we find that it does not correctly predict the phonon lifetimes because it does not capture the total phonon spectral energy density.

2 Phonon Spectral Energy Density

2.1 As Derived from Normal Mode Coordinates, $\Phi$

The correct expression for the phonon SED, $\Phi$, can be derived from the formulation of anharmonic lattice dynamics theory $[3–6]$. As shown in Ref. $[48]$, the phonon SED at wave vector $\mathbf{k}$ is a function of frequency, $\omega$, and is given by

$$
\Phi(\mathbf{k}, \omega) = \sum_{\nu} C_{0(\nu)}(\mathbf{k}) \frac{\Gamma(\mathbf{k}) / \pi}{[\omega_{0(\nu)}(\mathbf{k}) - \omega]^2 + \Gamma^2(\mathbf{k})},
$$

which is a superposition of $3n$ Lorentzian functions with centers at $\omega_{0(\nu)}(\mathbf{k})$ and line widths $\Gamma(\mathbf{k})$ (one for each polarization, $\nu$). The $C_{0(\nu)}(\mathbf{k})$ terms are mode-dependent constants. For simplicity, we refer to $\Phi(\mathbf{k}, \omega)$ as $\Phi$. The phonon kinetic energy
normal mode coordinate, $\dot{q}(\kappa; t)$, is [6]

$$
\dot{q}(\kappa; t) = \sum_{\alpha, b, l}^{3, n, N} \sqrt{\frac{m_b}{N}} \dot{u}_{\alpha}(l; t) e^{\ast}(b, \alpha) \exp\{i\kappa \cdot r_0(\alpha)\},
$$

(2)

where $e^{\ast}(b, \alpha)$ are the components of the time-independent phonon mode eigenvector (see Section 3.2), $n$ is the number of atoms in the unit cell, $m_b$ is the mass of the $b^{th}$ atom in the unit cell and $r_0(\alpha)$ is the equilibrium position vector of the $l^{th}$ unit cell. There are $N$ total unit cells and $\dot{u}_{\alpha}(l; t)$ is the $\alpha$-component of the velocity of the $b^{th}$ atom in the $l^{th}$ unit cell at time $t$.

Given a set of atomic velocities from MD simulation and the phonon mode eigenvector, $\Phi$ can be calculated using

$$
\Phi(\kappa, \omega) = 2 \sum_{\nu}^{3n} T(\kappa; \omega) = 2 \sum_{\nu}^{3n} \lim_{\tau_0 \to \infty} \frac{1}{2\tau_0} \left| \frac{1}{\sqrt{2\pi}} \int_{0}^{\tau_0} \dot{q}(\kappa; t) \exp(-i\omega t) dt \right|^2,
$$

(3)

and then fit using Equation (1) to extract the phonon properties $\omega_0(\kappa)$ and $\Gamma(\kappa)$ [48]. The phonon lifetime, $\tau_0(\kappa)$, is defined as $1/[2\Gamma(\kappa)]$. In practice, $\tau_0$ should be much larger than the longest phonon lifetime and the continuous Fourier transform in Equation (3) is performed using a discrete fast Fourier transform (see Sections 4.1, 4.2 and 4.3).

Previous work using normal mode analysis has represented the phonon energy in the time domain [24, 25, 28, 32, 35, 36], while $\Phi$ is a representation of the phonon energy in the frequency domain. The time- and frequency-domain approaches are mathematically equivalent by use of the Wiener-Khinchin theorem [40, 49]. The frequency-domain approach has the advantage of predicting both the phonon lifetime
and frequency by fitting a simpler function than is required in the time-domain approach.

2.2 Alternative Formulation, \( \Phi' \)

We now seek to motivate the expression \( \Phi' \) that was proposed in previous studies but has not been validated [37–39]. Thomas et al. [39] define

\[
\Phi' (\bm{\kappa}, \omega) = \frac{1}{4\pi \tau_0} \sum_{\alpha} \sum_{\beta} \frac{m_b}{N} \left| \sum_{l} \int_{0}^{\tau_0} \dot{u}_{\alpha \beta} (l; t) \exp[\Theta] dt \right|^2 , \tag{4}
\]

where \( \Theta \equiv i[\bm{\kappa} \cdot \bm{r}_{0\beta}(l) - \omega t] \). To understand this expression, we start with the real-space atomic velocities as represented by the normal mode velocities, \( \dot{q} (\kappa'_\nu; t) \) [6],

\[
\dot{u}_{\alpha \beta} (l; t) = \sum_{\kappa' \nu} \frac{1}{2 \sqrt{m_b N}} \exp \left[ i \kappa' \cdot \bm{r}_{0\beta}(l) \right] c^* (\kappa'_\nu \alpha) \dot{q} (\kappa'_\nu; t) . \tag{5}
\]

Fourier transforming both sides of Equation (5) in time and space, taking the complex modulus, and summing over the atoms in the unit cell and the Cartesian directions yields

\[
\lim_{\tau_0 \to \infty} \frac{1}{4\pi \tau_0} \sum_{\alpha} \sum_{\beta} \frac{m_b}{N} \left| \sum_{l} \int_{0}^{\tau_0} \dot{u}_{\alpha \beta} (l; t) \exp[\Theta] dt \right|^2 =
\]

\[
\lim_{\tau_0 \to \infty} \frac{1}{4\pi \tau_0} \sum_{\alpha} \sum_{\beta} \frac{m_b^{3/2}}{\sqrt{N}} \sum_{l} \sum_{\nu} \sum_{\alpha} \sum_{\nu} e^{\ast (\kappa' \nu \alpha)} \int_{0}^{\tau_0} \dot{q} (\kappa'_\nu; t) \exp[\Theta] dt \right|^2 , \tag{6}
\]
where the the sum over $\kappa'$ on the right-hand-side is reduced to a single wave vector by the orthogonality of the allowed wave vectors over the periodic domain. Equation (4) is the finite integration of the left-hand-side of Equation (6). For simplicity, we refer to $\Phi'(\kappa, \omega)$ as $\Phi'$. Given a set of atomic velocities, Thomas et al. extract the phonon properties $\omega_0(\kappa)$ and $\tau(\kappa)$ from Equation (4) by fitting $\Phi'$ for a given wave vector to a superposition of Lorentzian functions.

Thomas et al. [39] claim that $\Phi'$ represents the phonon SED. As seen in Equation (5), the phonon mode eigenvectors are necessary to properly map between the atomic velocities and the normal mode coordinates. This need for the eigenvectors is the essential difference between the expressions for $\Phi$ and $\Phi'$. The potential advantage of $\Phi'$ is that other than the wave vectors, which can be determined from the crystal structure, no phonon properties need to be known a priori. However, to identify the degenerate modes in $\Phi'$, the phonon frequencies are necessary (see Section 3.2). Since $\Phi'$ does not require the phonon mode eigenvector, it can (in principle) be used to study disordered systems or perturbed crystalline systems (e.g. dilute alloys [42], water-filled CNTs [39], and CNTs on substrates [40]). Despite its use in previous studies, $\Phi'$ has not been rigorously validated.

3 Computational Details

3.1 Allowed Wave Vectors

Now that we have presented the two expressions for the phonon SED, we will provide the computational details of how they can be evaluated and used to predict phonon
properties. The SED is defined for the allowed wave vectors of a crystal, which can be specified from the crystal structure’s Bravais lattice, its basis (i.e., unit cell), and the size of the computational domain. A $D$-dimensional Bravais lattice is a collection of points with positions

$$
\mathbf{r}_{0(l_0)} = \sum_{\alpha} N_{\alpha} \mathbf{a}_{\alpha},
$$

(7)

where $\mathbf{a}_{\alpha}$ are the lattice vectors and $N_{\alpha}$ is an integer [6]. The unit cell is the building block of the crystal and is placed on the points defined by the Bravais lattice. The equilibrium position of any atom in the crystal can be described by

$$
\mathbf{r}_{0(l_b)} = \mathbf{r}_{0(l_0)} + \mathbf{r}_{0(0_b)},
$$

(8)

where $\mathbf{r}_{0(0_b)}$ is the equilibrium position of the $b^{th}$ atom in the unit cell relative to $\mathbf{r}_{0(l_0)}$. The allowed wave vectors for any crystal structure are defined by

$$
\mathbf{k} = \sum_{\alpha} b_{\alpha} \frac{n_{\alpha}}{N_{\alpha}},
$$

(9)

where $b_{\alpha}$ are the reciprocal lattice vectors and $-N_{\alpha}/2 < n_{\alpha} \leq N_{\alpha}/2$, where $n_{\alpha}$ are integers and $N_{\alpha}$ are now constant even integers. The wave vectors are taken to be in the first Brillouin zone [45].

For the LJ argon and SW silicon systems studied here, the cubic conventional cells are used with four (argon) and eight (silicon) atoms per unit cell. For the MD simulations of LJ argon and SW silicon, cubic simulation domains are used (i.e.,
\( N_1 = N_2 = N_3 = N_0 \) [25, 27, 28]. For the CNT, the Brillouin zone is one-dimensional, so that \( N_1 = N_2 = 1 \), and we take \( N_3 = 50 \) [39].

### 3.2 Phonon Lifetimes and Frequencies

Once the allowed wave vectors are specified, the atomic velocities from an MD simulation can be used to calculate \( \Phi' \) using Equation (4). To calculate \( \Phi \) [Equation (1)], Equation (3) and (12) of Ref. [48] require the phonon mode eigenvector, which can be obtained using harmonic lattice dynamics calculations and the finite temperature lattice constant (i.e., quasi-harmonic lattice dynamics calculations) [6]. The \( \Phi \) and \( \Phi' \) methods can be used for any material system where there are available interatomic potentials.

The phonon frequencies and lifetimes are found by fitting the spectral curves \( \Phi \) and \( \Phi' \) with Lorentzian functions using a non-linear least squares method. Both of these phonon properties are independent of the Lorentzian peak magnitude. For \( \Phi' \), the different polarizations at a given wave vector are superimposed by definition of Equation (4). The different polarizations can be fit individually using single Lorentzian peaks or as a superposition of peaks. At high temperatures, the broadening of the peaks from different polarizations can make it difficult to uniquely locate the peaks in \( \Phi' \). Knowledge of the quasi-harmonic frequencies is necessary to identify the unique peaks in \( \Phi' \) as well as degeneracies [28, 50].

\( \Phi \) has the advantage that degenerate and nearly degenerate polarizations can be isolated and fit individually. The uncertainty in the predicted phonon frequencies is on the order of the frequency resolution used to perform the fast Fourier transforms.
required to evaluate $\Phi$ and $\Phi'$, which is $10^2 - 10^4$ less than the phonon frequencies studied in this work (see Sections 4.1, 4.2, and 4.3). At the temperatures studied in this work, we find that fitting single or simultaneous peaks in either $\Phi$ or $\Phi'$ results in less than five percent difference in the predicted lifetimes. The uncertainty from fitting the Lorentzian functions is between five and ten percent of the predicted lifetimes, with the error increasing with increasing temperature.\footnote{The range of data must be selected when fitting the Lorentzian functions to $\Phi$ or $\Phi'$. This range should be large enough for the Lorentzian functions to decrease significantly from their value at half-width at half-maximum, where the line width is specified, but not too large as to pick up noise. The error in predicting the lifetime is obtained by varying the range of data used to fit the Lorentzian function.}

To illustrate the procedure, $\Phi$ was calculated for LJ argon (Section 4.1) with $N_0 = 8$ and $T = 20$ K, where $T$ is temperature. $\Phi$ for the three modes of lowest frequency and wave vector $[\pi/4a, \pi/4a, \pi/4a]$ is shown in Fig. 1. The lower-frequency peak corresponds to the two degenerate transverse acoustic modes, while the higher frequency peak corresponds to the longitudinal acoustic mode [6].

### 3.3 Thermal Conductivity

Once the frequencies and lifetimes of all phonon modes in the first Brillouin zone are obtained, the bulk thermal conductivity in direction $n$, $k_n$, can be calculated from [51]

\[
k_n = \sum_k \sum_\nu c_{\nu, n}(k) v^2_{\nu, n}(k) \tau(k).
\]
Figure 1: The SED (using $\Phi$) for the first three polarizations at the wave vector $[\pi/4a, \pi/4a, \pi/4a]$ for LJ argon at a temperature of 20 K. There are two degenerate transverse acoustic (TA) polarizations and one longitudinal acoustic (LA) polarization. When fitting the SED, the different polarizations can be fit individually using single Lorentzian peaks or as a superposition of polarizations. Here the two peaks are fit individually with $\Phi$ plotted as a superposition. The predicted lifetimes, which are inversely proportional to $\Gamma$ are provided in the legend.
Here, $c_{ph}$ is the phonon volumetric specific heat and $v_{g,n}$ is the component of the group velocity vector in direction $n$. Since the systems we consider are classical and obey Maxwell-Boltzmann statistics \[52\], the specific heat is $k_B$ per mode in the harmonic limit, where $k_B$ is the Boltzmann constant. As temperature increases, anharmonicity causes the mode specific heats to deviate from $k_B$ \[25\]. The effect is small for the systems and temperatures studied here. For LJ argon, the mode-averaged specific heat has been predicted to be $0.95k_B$ per mode at a temperature of 40 K and approaches $k_B$ with decreasing temperature \[25\]. For SW silicon at a temperature of 300 K, the predicted mode-averaged specific heat is $1.01k_B$ per mode \[36\]. For the CNT at $T = 300$ K, we predict the mode-averaged specific heat to be $1.03k_B$ per mode. Because we do not have mode-dependent specific heats, we take the specific heat to be $k_B$ per mode for the three systems studied (argon, silicon, and CNT). The group velocity vector is the gradient of the dispersion curve (i.e., $\partial \omega / \partial \kappa$) and can be calculated from the frequencies and wave vectors using finite differences. In this work, the group velocities are calculated using the frequencies from quasi-harmonic lattice dynamics calculations because a smaller finite difference in wave vector can be used than what is available from the MD simulations (see Section 3.1).\(^2\)

\(^2\)The anharmonic frequency shift affects the group velocity. McGaughey and Kaviany find that anharmonic and quasi-harmonic predictions of the group velocity differ for LJ Argon by less than one percent at a temperature of 50 K and that the difference decreases with decreasing temperature \[25\]. The anharmonic frequency shifts are on average a few percent for LJ argon at a temperature of 40 K and are less for the other temperatures and systems studied here.
3.4 Computational Cost

The computational cost of evaluating Equation (4) is less than that for Equation (1) by a factor of $3b$, where $b$ is the number of atoms in the unit cell. For bulk crystals, the number of atoms in the unit cell is typically small ($b < 10$). For the (8,8) CNT system, $b = 32$ and evaluating $\Phi'$ is two orders of magnitude less expensive than evaluating $\Phi$.

To calculate the phonon lifetimes, the MD simulation time should be an order of magnitude longer than the longest phonon lifetime [53]. If only the phonon frequencies are required, however, the location of the peaks in $\Phi$ and $\Phi'$ develop in a time on the order of the inverse of the phonon frequency, $1/\omega_0(\nu)$. For the systems studied here, this time can be two to five orders of magnitude less than the time needed to develop the lifetimes.

Fitting $\Phi'$ becomes challenging at higher temperatures, when the phonon line widths broaden and become comparable to the spacing between mode frequencies. The cost of fitting $\Phi'$ can be reduced by fitting the peaks from all allowed wave vectors in the system simultaneously, but the error associated with this procedure is unknown [42]. We find that a semi-automated procedure, whereby the fits are visualized, is necessary to ensure that all peaks are fit correctly. While the computational cost of fitting $\Phi'$ is much smaller than the computational cost of calculating $\Phi'$, the semi-automated fitting procedure can be of similar time cost to the user. The cost of fitting $\Phi$ is much smaller because the different polarization peaks can be isolated and the fitting can be fully automated.
4 Case Studies

4.1 Lennard-Jones Argon

We now use MD simulation to compare the SED, phonon properties, and thermal conductivity calculated for LJ argon using $\Phi$ and $\Phi'$. The MD simulations are performed using LAMMPS [54]. A truncated and shifted potential cutoff scheme is used with a cutoff radius of 8.5 $\text{Å}$. The quasi-harmonic phonon frequencies, eigenvectors, and group velocities are generated using GULP [55]. We consider temperatures of 5, 20, and 40 K at zero-pressure with lattice constants of 5.278, 5.315, and 5.371 $\text{Å}$. For LJ argon, Turney et al. found that lattice dynamics-based predictions of thermal conductivity (e.g., by anharmonic lattice dynamics or $\Phi$) start to diverge from MD-based predictions (e.g., from the direct or Green-Kubo methods) above half the melting temperature ($T_{\text{melt}} \approx 80 \text{ K}$) [28]. Here, we limit the temperature to below half the melting temperature for the three systems studied (argon, silicon, and CNT).

The MD system consists of $N_1 \times N_2 \times N_3 = 8^3 = 512$ conventional cubic unit cells for a total of 2048 atoms ($b = 4$ atoms). Using a 4.285 fs time step, the system is equilibrated for $2^{20}$ time steps before collecting data every $2^5$ time steps for an additional $2^{20}$ time steps in the $NVE$ ensemble (constant number of atoms, system volume, and total system energy) [52]. The sampling rate must be high enough to capture the highest phonon frequency in the system. The sampling rate and total run time are chosen in powers of two as a convenience in performing the fast Fourier transforms required to efficiently evaluate $\Phi$ and $\Phi'$. The same MD simulation data
are used to calculate $\Phi$ and $\Phi'$. Five simulations with different initial conditions are performed and the $\Phi$ and $\Phi'$ values are averaged before the peak fitting. $\Phi$ and $\Phi'$ are further averaged over degenerate wave vectors in the Brillouin zone, reducing the wave vectors to the first octant [56].

The SED ($\Phi$ and $\Phi'$) for the wave vector $[\pi/2a, 0, 0]$ is presented in Fig. 2 for all three temperatures (the edge of the Brillouin zone is at $[\pi/a, 0, 0]$). For $\Phi$, the spectral curve is plotted as a superposition over the twelve phonon polarizations, with degeneracy reducing the number of peaks to seven. Overall, $\Phi'$ does not equal the total phonon spectral energy density $\Phi$, but the major features are similar. At all temperatures there are line width variations between the two spectral curves. The peak magnitudes become comparable for $\Phi$ and $\Phi'$ as the temperature increases.

The phonon frequencies and lifetimes extracted for all allowed wave vectors in the first Brillouin zone using $\Phi$ and $\Phi'$ at each of the three temperatures are compared on a mode-by-mode basis in Figs. 3(a), 3(b), and 3(c). There, $\omega_0$, $\omega'_0$, $\tau$, and $\tau'$ refer to the mode properties predicted using $\Phi$ and $\Phi'$. The phonon frequencies agree well at all three temperatures, with increasing scatter at high temperatures and high frequencies. This scatter is due to the high-frequency peak broadening seen in Fig. 2 at $T = 40$ K, which can force peaks close in frequency for $\Phi'$ to be fit as a single Lorentzian function. The frequencies predicted by $\Phi$ and $\Phi'$ include the effects of anharmonicity, which increase the frequencies compared to the quasi-harmonic predictions [25, 28]. The agreement between the frequencies predicted from $\Phi$ and $\Phi'$ is explained in Ref. [48].

The lifetimes show large scatter between $\Phi$ and $\Phi'$ on a mode-by-mode basis,
Figure 2: The phonon spectral energy density ($\Phi$) is plotted as larger blue circles. The proposed alternative expression for the phonon spectral energy density ($\Phi'$) is plotted as smaller green points. The wave vector is ($\pi/2a,0,0$). Note that peak broadening at higher temperatures and frequencies above 10 rads/ps can force peaks close in frequency for $\Phi'$ to be fit as a single Lorentzian function. $\Phi$ does not suffer from this issue since the broadened peaks can be fit individually.
with increasing scatter at high temperature that shows no systematic difference. The scatter at high frequencies is in part due to the peak broadening seen in Fig. 2, which can force peaks close in frequency for $\Phi'$ to be fit as a single Lorentzian function with a single lifetime. The broadening does not affect fitting at low frequencies, where the line widths are much smaller than the peak spacings. There, any scatter comes solely from the difference between $\Phi$ and $\Phi'$.

The phonon properties are then used to predict thermal conductivity using Equation (10). The results are presented in Table 1. The bulk thermal conductivities provided in Table 1 are predicted using the finite simulation-size scaling procedure discussed in [28]. The bulk thermal conductivities predicted from $\Phi'$ are smaller and outside the uncertainty for those predicted from $\Phi$ for temperatures of 5 and 20 K. While the bulk thermal conductivities at a temperature of 40 K agree within their uncertainties, the predicted mode-by-mode lifetimes show large scatter [Fig. 3(c)] and the agreement should be regarded as coincidental.

The disagreement between $\Phi$ and $\Phi'$ in thermal conductivity comes directly from the differences in the phonon lifetimes. All other properties (frequencies, group velocities, specific heats) are nearly or exactly the same for the two calculations. The bulk thermal conductivities predicted from $\Phi$ and $\Phi'$ are also compared to predictions from the Green-Kubo method[52] in Table 1. For $N_1 = N_2 = N_3 = 8$, the thermal conductivity predicted by the Green-Kubo method is converged with respect to the simulation size [25]. The same MD data used to calculate $\Phi$ and $\Phi'$ is used for the Green-Kubo predictions. For all three temperatures, there is good agreement between the thermal conductivity predictions using $\Phi$ and Green-Kubo.
Figure 3: Comparison of the phonon frequencies and lifetimes predicted using $\Phi (\omega$ and $\tau)$ and $\Phi' (\omega'$ and $\tau')$ for LJ argon at temperatures of (a) 5 K, (b) 20 K, and (c) 40 K. The phonon frequencies agree well at all three temperatures, while the phonon lifetimes show large scatter.
Table 1: Thermal conductivity values in W/m-K predicted using the Φ, Φ′, and Green-Kubo methods. The predictions for Φ and Green-Kubo for the LJ system are in good agreement with those from other atomistic simulation methods[28] while those from Φ′ differ and show no consistent behavior. The uncertainties in the predicted thermal conductivities for Φ and Φ′ come predominantly from the finite simulation-size scaling procedure (see Ref. [28, 32]), where the phonon properties and thermal conductivity are predicted for increasing system sizes ($N_1 = N_2 = N_3$) to extrapolate a bulk thermal conductivity. For SW silicon and the CNT, the extrapolation procedure is not performed.

For temperatures of 20 and 40 K, there is good agreement between the predictions from Φ, Green-Kubo, and previous reports using non-equilibrium MD, anharmonic lattice dynamics, and time-domain Φ [28].

### 4.2 Stillinger-Weber Silicon

We next compare the phonon properties and thermal conductivity predicted from Φ and Φ′ for SW silicon [46] at a temperature of 300 K and zero pressure with a lattice constant of 5.437 Å. The SW system is stiffer (larger phonon group velocities, frequencies, and lifetimes) than LJ argon and is an additional test to determine if
there is a systematic error in the predictions from $\Phi'$. The MD simulations are performed using LAMMPS [54]. The MD system consists of $N_1 \times N_2 \times N_3 = 6^3 = 216$ conventional unit cells for a total of 1728 atoms ($b = 8$ atoms). The phonon frequencies, eigenvectors, and group velocities are generated using GULP [55].

Using a 0.5 fs time step, the system is equilibrated for $2^{20}$ time steps before collecting data every $2^5$ time step for $2^{22}$ time steps in the $NVE$ ensemble [52]. As with the LJ system, the sampling rate is determined by the highest phonon frequency in the system. Five simulations with different initial conditions are performed and the $\Phi$ and $\Phi'$ values are averaged before the peak fitting. $\Phi$ and $\Phi'$ are further averaged over degenerate wave vectors in the Brillouin zone, reducing the wave vectors to the first octant [56].

The extracted phonon frequencies and lifetimes are plotted in Fig. 4. As with the LJ system, the phonon frequencies are predicted accurately by $\Phi'$ but the lifetimes show large scatter on a mode-by-mode basis. For the system size studied, $\Phi'$ predicts a larger thermal conductivity than $\Phi$ outside the prediction uncertainties, in contrast to the LJ system (see Table 1). The disagreement in thermal conductivity comes directly from the phonon lifetimes.
Figure 4: Comparison of the phonon frequencies and lifetimes predicted using $\Phi$ ($\omega$ and $\tau$) and $\Phi'$ ($\omega'$ and $\tau'$) for SW silicon. The phonon frequencies agree well, while the phonon lifetimes show large scatter.
4.3 Carbon Nanotube

Finally, we compare the phonon properties and thermal conductivities predicted by $\Phi$ and $\Phi'$ for an (8,8) CNT (diameter of 1.10-nm and length of 12.3 nm) at a temperature of 300 K and zero pressure [39]. The interactions in the CNT system are modeled using the REBO potential without the four-body interaction term [47]. The MD simulations are performed using an in-house code. The MD system consists of 1600 atoms (32 atoms/unit cell). The phonon frequencies, eigenvectors, and group velocities are generated using an in-house code. The purpose of simulating this system is to check the results of Thomas et al.[39] (who used $\Phi'$ and non-equilibrium MD), and to compare the predictions of $\Phi'$ and $\Phi$.

Using a 1.0 fs time step, the system is equilibrated for $2^{20}$ time steps before collecting data every $2^3$ time step for $2^{22}$ time steps in the $NVE$ ensemble [52]. As with the LJ and SW systems, the sampling rate is determined by the highest phonon frequency in the system. Five simulations with different initial conditions are performed and the $\Phi$ and $\Phi'$ values are averaged before the peak fitting. Since the Brillouin zone of the CNT is one-dimensional, $\Phi$ and $\Phi'$ are further averaged over directionally-degenerate wave vectors.

The phonon frequencies and lifetimes for the allowed wave vectors in the one-dimensional Brillouin zone are shown in Fig. 5. Like the LJ and SW silicon systems, the phonon frequencies can be predicted accurately by $\Phi'$, but the lifetimes show large scatter. The estimated thermal conductivity of the CNT predicted using $\Phi'$ is in agreement with the results of Thomas et al. [39]. The thermal conductivity predicted by $\Phi'$ is less than that predicted by $\Phi$, but not outside their uncertainties.
Figure 5: Comparison of the phonon frequencies and lifetimes predicted using $\Phi (\omega, \tau)$ and $\Phi' (\omega', \tau')$ for a (8,8) CNT modeled using the REBO potential. The phonon frequencies agree well, while the phonon lifetimes show large scatter.

5 Summary

We presented the correct phonon SED, $\Phi$, and its relation to the phonon frequencies and lifetimes. We then presented an alternative formulation to the phonon spectral energy density, $\Phi'$, which does not require the phonon mode eigenvectors. Because $\Phi'$ does not contain the eigenvectors, this alternative formulation does not represent the phonon spectral energy density, but does contain information about the phonon dispersion as the temperature approaches 0 K (see Ref. [48]).

We then calculated the phonon SED for LJ argon, SW silicon, and a CNT modeled with the REBO potential using $\Phi$ and $\Phi'$. The phonon frequencies and lifetimes predicted from $\Phi$ and $\Phi'$ are shown in Figs. 3, 4 and 5. The frequencies are in good agreement between the two SED methods, while the lifetimes show large scatter.
The phonon SED $\Phi$ is well-defined theoretically, while $\Phi'$ does not properly map to the phonon energies since it is missing the phonon mode eigenvector. We deduce that this is the reason $\Phi'$ does not accurately predict the phonon lifetimes. It is surprising how close the predicted thermal conductivities can be using $\Phi$ and $\Phi'$ (LJ at $T = 40$ K and the CNT results). The thermal conductivities predicted by $\Phi$ and $\Phi'$, however, show no consistency for the three systems studied.

The most important predictions are the mode-by-mode phonon properties. Of particular importance are the lifetimes, which are the key input for Boltzmann transport equation-based models [18]. Thus, we do not recommend $\Phi'$ for predicting phonon lifetimes or thermal conductivity. Any agreement in thermal conductivity predictions between atomistic studies[39] and experiment[41, 43] should be regarded as coincidental, and the phonon lifetime reductions predicted for systems with additional scattering methods [39, 42] should only be interpreted qualitatively. The use of $\Phi'$ in future work is discouraged and we recommend the use of $\Phi$.
